

## **An Unequal Adaption to Climate Change**

### **What is the issue?**

\n\n

\n

- There are ongoing efforts to reduce greenhouse gas emissions and restrict global warming to below 2°C or even below 1.5°C.

\n

- Simultaneously, there are also efforts in many countries on projects developing adaptation techniques to cope with rising average global temperatures.

\n

\n\n

### **What is the problem with Adaptation Projects?**

\n\n

\n

- Many adaptation projects study what climate impacts are expected, what kinds of vulnerabilities exist locally and how these can be addressed.

\n

- But a 2010 survey covering over 1,700 projects concluded that adaptation projects were mostly elite centric and didn't focus on the vulnerable.

\n

- The 'Global Adaptation Fund', managed by the UN climate secretariat also runs projects to assist developing countries adapt to climate adversaries.

\n

- Even these projects were not accounting for unequal power structures, with the well off cornering most of the limited allocated resources.

\n

- When failures of adaptation projects were studied, most of it fell into one of the four main headers that were discovered.

\n

\n\n

### **What are the four headers?**

\n\n

- \n
- The first is enclosure, which is when private agents acquire public assets or expand their authority over them, to the deprivation of the rest.
- \n
- Exclusion is the second mode of failure, which is associated with some stakeholders getting excluded or marginalised in the scheme of things.
- \n
- The third is encroachment, in which the adaptation actions undertaken during the project end up intervening in areas that are rich in biodiversity.
- \n
- This thereby interferes with the ecosystem's natural services and often results in an increase in greenhouse gas emissions.
- \n
- The last is entrenchment, where the condition worsens for those who are already disempowered or marginalised in the local social context.
- \n
- This includes the poor, women or other minorities and the disabled.
- \n

\n\n

### **What are some projects that can be classified under the above headers?**

\n\n

- \n
- There are various examples of projects from both developing and advanced industrial countries that fail under these themes.
- \n
- A private desalination plant was constructed in Melbourne (Australia), by government seizure of land from the Bunurong aboriginal community.
- \n
- In Norway, the representation of community organisations and environmental groups were low during the coastal planning process.
- \n
- Hence, their concerns, ideas and aspirations couldn't be voiced effectively.
- \n
- In Alaska, the Army Corps and private contractors built a barrier against the sea even though this was against the wishes of the local community.
- \n
- In Tanzania marine protection areas were set up to boost the resilience of coral reefs by encroaching on the lands of traditional fishing communities.
- \n
- Interestingly, this forced them to turn resort to energy-intensive farming for a livelihood, which led to higher rates of greenhouse gas emissions.
- \n

- Disaster relief funds provided to cities first led to crises in rural communities in Kenya and also led to political unrest.  
\n
- Notably, all these situations may also result in multiple harmful effects, and can be classified under multiple headers.  
\n

\n\n

### **Why excessive stress on Tech-centric solutions is a strain?**

\n\n

- There has been a tendency to identify climate impacts and then regard technology as the straightforward solution.  
\n
- For example, use drip irrigation or watershed development to increase water availability, or building barriers along the shore for protection from storms.  
\n
- The problem in such an approach is that the 2<sup>nd</sup> order ramifications and worsening of social and political conditions of the masses are usually ignored.  
\n
- Thus, adaption projects, in addition to vulnerabilities and costs, should also consider justice and social hierarchies in its very design.  
\n
- Otherwise, existing social, economic, ecological and political problems might get aggravated.  
\n

\n\n

### **What is the way forward?**

\n\n

- Power struggles to control resources need to be acknowledged as indispensable and mechanisms to anticipate and deal with them correctly needs to be built.  
\n
- These are needed to prevent elitist capture of resources as land, water and other privileges like being involved in decisions needs to be shared with all.  
\n
- A thorough analysis of stakeholders' interests and power relationships between allies and competitors are hence vital in adaptation projects.  
\n

- **India's case** - India is a deeply stratified society with entrenched elite networks and growing levels of inequality and a burgeoning population.  
\n
- Additionally, multiple adaptation projects are being carried out in India, considering its geography and particularly significant climate vulnerability.  
\n
- Hence, anticipating problems and trying to reduce the adverse effects with the ultimate aim to reduce the effects of global warming are needed.
