

Bats in Plantations

Why in news?

\n\n

A recent study shows that tea plantations in the Western Ghats hosts less-diverse bat communities than those found in coffee estates and forests.

\n\n

What are the findings of the study?

\n\n

\n

- Forests in Western Ghats have changed drastically.

\n

- The study examined bat diet, echolocation, body size and wing morphology in different habitats in Valparai, Western Ghats.

\n

- In Valparai tea and coffee plantations have fragmented natural forests.

\n

- It found that tea plantations fared badly.

\n

- Only few insectivorous bats that could adapt to highly modified habitats thrived here.

\n

- Coffee plantations did better because of native tree presence which is required for coffee growth.

\n

- Protected areas and forest fragments were the most 'functionally' rich, by being home to bats with diverse morphologies.

\n

\n\n

What is the significance of bats?

\n\n

\n

- Bats perform important ecological functions.

\n

- They are important insect controllers, pollinators and seed-dispersers.
\n
- Different bat species can perform these varied ecological functions due to the physical features they have evolved.
\n
- e.g Bats with short, broad wings are better suited to plucking off large insects on the wing, in densely-vegetated patches like the forests of the Ghats.
\n

\n\n

What should be done?

\n\n

- \n
- Tea plantations will never be as rich for wildlife as coffee plantations.
\n
- But it can be more biodiversity-friendly if small changes in land use practices is implemented.
\n
- Bats and other fauna could benefit if tea plantations have a buffer of native trees on both sides of every river.
\n
- Protecting existing forest fragments and extending them wherever possible could also help.
