

## Resilience Planning - Kerala Floods

### What is the issue?

\n\n

\n

- Kerala is witnessing historic rainfalls in disastrous proportions, with South west monsoon.

\n

- The impact of the flood has highlighted the need for governments to strengthen resilience planning.

\n

\n\n

### What is the catastrophic impact?

\n\n

\n

- Monsoon rainfall on several districts of Kerala has come as a reminder of unpredictable natural disasters.

\n

- More than three dozen people have died.

\n

- An estimated Rs. 8,000 crore worth of economic assets had been lost.

\n

- The gates of reservoirs in the Idukki system, and several other dams have been opened. Click [here](#) to know more

\n

- This has inundated the habitations downstream.

\n

- About 60,000 people whose dwellings suffered damage were lodged in relief camps.

\n

- Landslips caused by incessant showers have caused damage to houses, roads and other structures.

\n

\n\n

### What is the changing climate scenario?

\n\n

\n

- Kerala's unusually heavy monsoon this year is in contrast to the long-period trend of rainfall.

\n

- According to an analysis of data on the monsoon between 1954 and 2003, overall this part of the country had become drier in summer.

\n

- Nevertheless, there is an emerging frequency of destructive flash floods in rare events as this.

\n

- This trend is only expected to become stronger in the coming period.

\n

\n\n

### **How to deal with it?**

\n\n

\n

- With its efficient primary health care network, Kerala can take all measures to avoid epidemics.

\n

- However, the evolving climate pattern points to the need for governments to strengthen their resilience planning.

\n

- It should begin with a programme to relocate people away from hazard zones along the rivers.

\n

- But finding suitable land is a challenge in a populous, forested State as that of Kerala.
