

## Risks in Shale Gas Extraction

### What is the issue?

\n\n

\n

- Fracking is the technique used for extracting hydrocarbon resources from 'shale reservoirs' by drilling deep horizontal wells.

\n

- But there is considerable evidence to suggest that this method is detrimental to the environment, and governments need to exercise restraint.

\n

\n\n

### What are shale reservoirs?

\n\n

\n

- Apprehensions that fossil fuels will be depleted by 2050 have been challenged by some experts who've argued that there are still vast unexplored reserves.

\n

- Among the reserves that count for augmenting energy supplies is 'shale gas' and 'shale oil' both of which are estimated to be abundant underground.

\n

- Hydrocarbons are conventionally found at about 1,500 m depth, but shale gas and oil are usually found at depths of about 2,500-5,000 m.

\n

- They are classified as an unconventional hydrocarbon source and their extraction requires deep vertical drilling followed by horizontal drilling.

\n

\n\n

\n

- **Pioneers** - In the U.S., shale gas has been commercially exploited for two decades, and which has caused their fuel costs to drop considerably.

\n

- Shale discovery has also benefitted the US politically, as it effectively destroyed the clout of "Organisation of the Petroleum Exporting Countries" (OPEC).

- \n
- Similarly, if India commercially exploits shale deposits, it could meet its ever-increasing energy demand, and decrease its fuel import bills.

\n

\n\n

\n\n

## What is fracking?

\n\n

- \n
- Unlike conventional reservoirs, porosity of shale is very less - which therefore gives out little flow output after merely perforating (opening) the well.
- \n
- Hence, to increase the porosity of the reservoir and facilitate flows, the reservoir rock is fractured by using 'hydraulic fracturing' (fracking).
- \n
- In this method, high volumes of water mixed with certain chemicals are pushed down the well, to break the rocks and release the trapped resource.
- \n
- Fracking has proved to be an economically viable tool in extracting shale gas.

\n

- **India's case** - The government introduced a policy on shale gas and oil in 2013, permitting national oil companies to engage in fracking.

\n

- Under the first phase, shale gas blocks were identified in Andhra Pradesh, Arunachal Pradesh, Assam, Gujarat, Rajasthan and Tamil Nadu.

\n

- However, environmental groups have strongly criticised this move, which they say will have adverse environmental impacts.

\n

- Notably, countries like Germany and France and subnational governments like Scotland have banned fracking.

\n

\n\n

## **What are the environmental risks of fracking?**

\n\n

\n

- Fracking consumes large amounts of water (about 1.5 crore lts/well) and is bound to impact irrigation and other local requirements.

\n

- Additionally, this water is mixed with as much as 260 chemicals and pumped into the reservoir at high pressure to create cracks in the rocks.

\n

- The US experience shows that as many as 260 chemicals were used, of which 83 have been identified to pose a risk to human life and environment.

\n

- The disposal of the water used for fracking is another big challenge as such vast quantities has to be reprocessed before draining them out.

\n

- Further, about 25-90% of the fluid that is pumped in is lost within the reservoir and is not retrieved back.

\n

- This unrecoverable volume hence puts the nearby underground water sources at a high risk of contamination - some cases have already been documented.

\n

- Fracking also has other impacts such as increased air emissions (including greenhouse gases) and seismic activity - as recognized by some EU studies.

\n

- While some do contest the risks of fracking, the evidence currently seems to be pointing otherwise, which hence calls for a rethink.
