

Saraswati - A Supercluster Galaxy

Why in news?

\n\n

Indian astronomers discovered Supermega River of galaxies.

\n\n

What is it?

\n\n

\n

- A team of Indian astronomers has identified a cosmic behemoth - a supercluster of galaxies - about 4 billion light- years away from us

\n

- The new discovery has been named saraswati.

\n

- The supercluster spans over 650 million light years in its expanse, containing over 10,000 galaxies in 42 clusters.

\n

\n\n

\n\n

Why is it important?

\n\n

\n

- The discovery is forcing astronomers to rethink about early stages of the evolution of the universe.

\n

- It also provides vital clues about the mysterious dark matter and dark energy.

\n

- The saraswati supercluster clearly stands out in the sky as an especially rare, and possibly among the mega superclusters exceeding 500 million light years in size.

\n

- A large scale structure this massive evolves very slowly.

\n

- Therefore it may reflect the whole history of galaxy formation and the primordial initial conditions that have seeded it.

\n

\n\n

How it challenges current model?

\n\n

\n

- The long-popular “cold dark matter” model of evolution of universe predicts that small structures like galaxies form first, which congregate into larger structures.

\n

- The existence of large structures such as the “Saraswati Supercluster” that evolved as early as 10 billion years since the big bang is a challenge to this model.

\n

- Thus forces astronomers into re-thinking popular theories of how the universe got its current form.

\n

- Our work will help to shed light on the perplexing question how such extreme large scale, prominent matter-density enhancements had formed billions of years in the past when the mysterious Dark Energy had just started to dominated structure formation.

\n

\n\n

\n\n

What are super clusters?

\n\n

- \n
- It is a large group of smaller galaxy clusters or galaxy groups
- \n
- It is among the largest-known structures of the cosmos.
- \n
- The Milky Way is part of the Local Group galaxy cluster (that contains more than 54 galaxies), which in turn is part of the Laniakea Supercluster.
- \n
- This supercluster spans over 500 million light-years, while the Local Group spans over 10 million light-years.
- \n
- The number of superclusters in the observable universe is estimated to be 10 million.
- \n

\n\n

What is Sloan Digital Sky Survey?

\n\n

- \n
- The **Sloan Digital Sky Survey** or **SDSS** is a major multi-spectral imaging and spectroscopic redshift survey by USA
- \n

\n\n

\n

\n

A **redshift survey** is a survey of a section of the sky to measure the redshift of astronomical objects: usually galaxies, but sometimes other objects such as galaxy clusters or quasars.

\n

\n

\n\n

\n

- It is an ambitious plan to make a digital 3D map of the universe.

\n

- It started in the year 2000, and over eight years it mapped more than a quarter of the sky.

\n

- It has mapped nearly 930,000 galaxies. The SDSS has found nearly 50 million galaxies so far.

\n

- In its third phase, SDSS-III, which started in 2008 and ended in 2014, gave out sets of data that were released in 2011, 2012 and 2013.

\n

- It produced a map of the North galactic cap and of three stripes in the South Galactic Cap and the central stripe is known as **Stripe 82**.
