Understanding Rupee Depreciation

What is the issue?

\n\n

\n
- The recent slide in the rupee’s value is particularly steep.
\n
- However, it is to be noted that it is part of a longer process of decline and requires holistic measures.
\n

\n\n

What are the recent developments?

\n\n

\n
- The recent depreciation of the rupee worries those who need to buy foreign exchange.
\n
- It has also caused panic in the stock markets, the decline in which partly reflects the exit of foreign investors.
\n
- This, in turn, further contributes to the rupee’s fall. Click here to know more.
\n
- It causes further trouble for companies that borrowed heavily in foreign currency, encouraged by lower interest rates abroad.
\n
- It adds to domestic inflationary pressures that are already rising with higher global oil prices.
\n

\n\n

How has the depreciation trend been?

\n\n

\n
- The period of the global financial crisis in 2008 witnessed rupee depreciation like many other emerging market currencies.

\n

- But this was relatively small and the recovery of the rupee was also relatively rapid.
  \n
- Thereafter, the currency was relatively stable in nominal terms until late 2011.
  \n
- From then on, it started declining relative to the US dollar once again.
  \n
- It culminated in a particularly sharp decline in the middle of 2013.
  \n
- This is famously referred to as the “taper tantrum” which afflicted all emerging markets.
  \n
- It happened when the US Federal Reserve hinted that the Fed might soon start tapering off the extraordinary liquidity creation measures.
  \n
- [Notably, the Quantitative Easing had marked the recovery strategy after the global crisis of 2008.]
  \n
- Now, vis-à-vis the US dollar, the rupee is worth only around half of its value in January 2008.
  \n
- This is a remarkably rapid nominal depreciation in just over a decade.
  \n

\n\n

What happened thereafter?

\n\n

\n

- Despite some slight recovery thereafter, the decline in the rupee’s value became a major political talking point.
  \n
- The performance of the currency from 2014 has not been so favourable.
  \n
- The rupee-dollar exchange rate had been deteriorating for the previous two years from the most recent sharp decline since January 2018.
  \n

\n\n

How was growth then?

\n\n

\n

- Despite the above, in this period, there were not much external headwinds to slow down the economic growth.
\n
- Evidently, the Indian economy was one of the major beneficiaries of low global oil prices.
\n
- It provided a windfall gain to the government since it did not pass on these declines to domestic consumers.
\n
- India was also a major recipient of portfolio capital inflows.
\n
- Also, more domestic companies took on external commercial debt.
\n
- Foreign exchange reserves also increased but the country continued to run a current account deficit.
\n
- So this was essentially based on short-term capital inflows.
\n
- Such a method of building up forex reserves is not sustainable or desirable.
\n
- Nevertheless, the significant level of reserves acts as a protection against capital flight and consequent rapid depreciation.
\n

\n\n

Can open market operations address depreciation?

\n\n

\n

- Open market operations (OMO) refer to the buying and selling of government securities in the open market.
\n
- This is primarily to expand or contract the amount of money in the banking system, to control liquidity.
\n
- It is argued that open market operations by the RBI could operate to stabilise exchange rates.
\n
- It is said to prevent excessive appreciation as well as protect against sharp depreciation.
\n
- However, previous episodes of currency volatility do not provide clear signals on the effects of OMOs.

\n

\n\n

\n

- Once market expectations have turned adverse, no amount of OMOs and no level of forex reserves had been “enough”.
\n
- Indeed, the very running down of reserves in the process of such intervention can further erode trust in the currency and undermine its value.
\n
- Thus OMOs are only more suitable in the “good times”, when it is necessary to prevent excessive appreciation of the currency.
\n

\n\n

What are the other measures?

\n\n

\n

- Given the above, a wider range of measures is required to tackle the depreciation crisis.
\n
- It makes more sense for policies to address the current account deficit.
\n
- E.g. controls on gold imports beyond those required for jewellery exports
\n
- On the other hand, capital account measures could seek to prevent outflows through transaction taxes.
