

Uranium Contamination in Ground Water

What is the issue?

\n\n

\n

- Reports of widespread uranium contamination in groundwater across India demand an urgent response.

\n

- Groundwater contamination across India must be probed and mapped, and safe sources need to be identified.

\n

\n\n

What is the scenario of uranium contamination?

\n\n

\n

- **Evidence** - A recent study, has found over 30 micrograms per litre (mcg/l) of the heavy metal in parts of north-western, southern and south-eastern India.

\n

- Reports of uranium contamination has cropped up across India in recent years, with south Bangalore recording 2000 mcg/l of uranium in groundwater.

\n

- Previously, regions of Andhra Pradesh and Telangana were found to have over 500 mcg/l of uranium in their aquifers.

\n

- More recently, parts of Gujarat and Rajasthan recorded undesirable uranium levels in their waters.

\n

- **Regulations** - Drinking such water can damage one's kidneys, and the World Health Organization (WHO) prescribes '30 mcg/l' as an upper limit.

\n

- But unfortunately, the residents of the regions surveyed were using wells recording far greater uranium levels as their main source of drinking water.

\n

- Significantly, as the "Bureau of Indian Standards" does not specify a norm for uranium level, water is not tested regularly for it.

\n

\n\n

What are the health effects?

\n\n

- \n
 - Preliminary studies on the health effects of drinking uranium-tainted water among animals and humans have revealed that it causes kidney damage.
 - \n
 - Notably, this is said to be caused by the chemical effect of uranium, rather than a radiological, even though uranium is radioactive.
 - \n
 - Nonetheless, we need more comprehensive systematic studies to establish the chronic health effects of uranium exposure.

\n\n

How does uranium enter ground water?

\n\n

- \n
 - The mechanism by which uranium enters groundwater is still under research.
 - \n
 - Two types of terrains have been identified with heavy contamination, namely:

\n\n

- \n
 - Alluvial aquifers in Rajasthan and other north-western regions
 - \n
 - Crystalline rocks such as granite in southern regions like Telangana.

\n\n

- \n
 - Some researchers have hypothesized that over-extraction of ground water exposes uranium to air, which triggers its release from the rocks.
 - \n
 - Further research is needed in this regard as it would help in identifying regions where safer water can be found.
 - \n
 - Notably, even information of how uranium accumulated with the rocks (during sedimentation), would help in estimating the regions of prevalence.
