

Water Crisis in Cape Town

What is the issue?

\n\n

\n

- The southern coastal city of Cape Town in South Africa is currently facing its worst drought in over 300 years, which has entered its 3rd year.

\n

- The region is also experiencing a long-term decline in average rainfall.

\n

\n\n

How bad is the situation?

\n\n

\n

- Reservoirs in Cape Town and surrounding areas now have water below their 25% mark.

\n

- The largest dam supplying water to the city, the “Theewaterskloof Dam”, is filled to only 11.3% of its capacity.

\n

- Water supply has already been reduced from about 1,200 million litres per day in 2015 to about 566 million litres per day now.

\n

- The city is fast approaching a situation where “water supply” to nearly 75% of the population would have to be cut.

\n

- Once such a situation is reached, water would then have to be rationed at some designated distribution points only.

\n

- Notably, residents of the city at present do not have more than 50 litres of water per person per day.

\n

\n\n

Is climate change the cause?

\n\n

\n

- It is difficult to ascertain the impact of climate change over a small geographical region.

\n

- But preliminary analysis suggests that three-year cumulative rainfall deficits have become five times more likely due to global warming.

\n

- The area has become prone to fluctuations in rainfall, and climate change does accentuate the variability.

\n

- But there is good reason to believe that Cape Town's case has significant links to larger changing climatic patterns.
