

Sewage and waste water are the main cause of river water pollution in India. While man made wetlands provides an effective solution to tackle it.

According to an article in Down to Earth more than 275 rivers in India are severely polluted mostly across - Assam, UP, MN, MP, etc. River Ganga, Yamuna which passes through industrial towns

pose challenge to

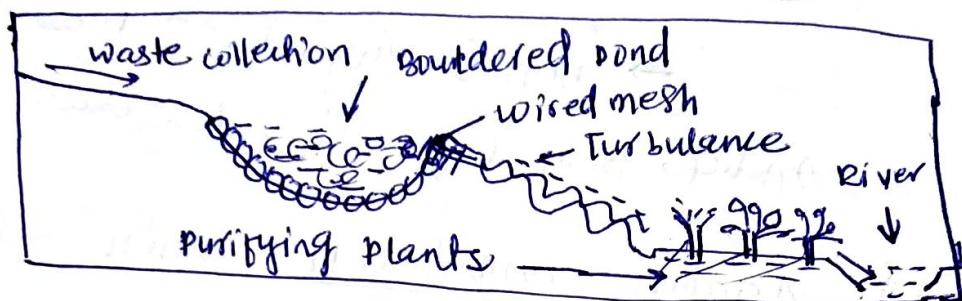

several government schemes like Namami Gange Yojna with 20,000 cr budget, to create modern & powered treatment plants gained limited success -

man made wetland technique which is adopted in South Delhi is most viable option.

As shown in figure it's a three stage process with

1st stage - is a pond made by using stones & boulders to collect non point source discharge. It opens into an oxidation pond where water is separated from waste using wired fence.

second stage - here the sewage is passed through a zig-zag land inclined towards sieves to create a turbulence. This is a aeration technique to increase O₂ content in sewage for decomposition and degassing.

3rd stage - here purifying plants are used to absorb toxic metals & compounds from sewage. The remaining is then discharged into river.

Benefits

(i) Laymen technique - can be made using mansega workers. easy to understand and build.

(ii) cost effective - does not require power at any stage and can be build using natural & local material.

(iii) environment freindly.

Thus such technique can play a suplementary and complementary roll in India's struggle towards swachh bharat.
